

AI Trading System — Where You Are & Where to Go Next

What You've Built So Far

Infrastructure (Solid Foundation ■)

Component	Status	What It Does
----- ----- -----		
Strategy Engine	■ Live	Scans BTC, Gold, Silver every 60s for EMA crossover signals
Bybit Executor	■ Connected	Places market orders on Testnet via V5 API
Grid-Search Optimizer	■ Working	Tests 945 param combos, validates on out-of-sample data
Offline Data Cache	■ Working	Stores 1000+ candles from Mainnet for instant backtests
Streamlit Dashboard	■ Deployed	Live prices, backtest panels, trade log, equity curve
GitHub Repo	■ Pushed	17 files, teammates can collaborate
Cloud Deployment	■■ Partial	Railway configured, needs domain fix

Current Strategy: EMA + RSI + Volume + ATR

...
BUY when: EMA(fast) crosses above EMA(slow) + RSI < 65 + Volume > 20-MA + Price > EMA(200)
SELL when: EMA(fast) crosses below EMA(slow) OR hit SL/TP
SL: Entry - ATR × 1.5 | TP: Entry + ATR × 3.0
...

Honest Assessment — What's Working & What's Not

■ What's Strong

- **Risk management** — ATR-based stops, position sizing, SL/TP built in
- **Anti-overfitting** — 70/30 train/test split in optimizer
- **Multi-asset diversification** — Not all eggs in one basket (BTC + Gold + Silver)
- **Auto re-optimization** — Self-corrects every 20 trades

■■ What's Weak (Critical Issues a Quant Would Flag)

Problem	Why It Matters	Severity
----- ----- -----		
Single strategy (EMA crossover)	This is the most basic trend-following strategy. Every retail trader uses it. Edge is near zero in 2026 markets.	■ Critical
No market regime detection	Your bot trades the same way in trending AND choppy markets. EMA crossovers get destroyed in sideways/range markets (whipsaw).	■ Critical
No order book / funding rate data	You're trading on lagging indicators only. Smart money uses order flow, funding rates, and open interest.	■ Important
No correlation filtering	BTC, Gold, Silver are correlated. In a risk-off crash, all 3 dump together — no diversification benefit.	■ Important
Backtest ≠ Reality	100% win rate in backtest means overfitting. Real slippage, fees, and latency will eat profits.	■ Critical
No drawdown circuit breaker	If the system loses 5 trades in a row, it keeps trading. Pro systems pause.	■ Important

Next Steps — The Quant Roadmap

Phase 1: Fix the Strategy Edge (Priority: NOW)

> Your current strategy will bleed money in real markets. Here's what a real quant system needs:

1. Add a Market Regime Filter

...

IF Volatility is HIGH ($ATR > 2 \times \text{average}$) → Use Breakout Strategy

IF Volatility is LOW ($ATR < 0.5 \times \text{average}$) → Use Mean Reversion Strategy

IF Market is TRENDING ($ADX > 25$) → Use Trend Following (your current EMA)

IF Market is CHOPPY ($ADX < 20$) → DO NOT TRADE (cash is a position)

...

****Why:**** This alone would eliminate 60-70% of losing trades from whipsaw.

2. Add a Second Signal Source (Mean Reversion)

Your current system only catches trends. Add a mean-reversion system for ranging markets:

...

BUY when: $RSI < 30$ + Price touches lower Bollinger Band + Volume spike

SELL when: $RSI > 70$ + Price touches upper Bollinger Band

...

3. Implement Proper Position Sizing

```python

**Current: Fixed 0.001 BTC every trade (wrong)**

**Better: Risk 0.5-1% of account per trade**

risk\_amount = balance \* 0.005

stop\_distance = entry\_price - stop\_loss

qty = risk\_amount / stop\_distance

...

---

## Phase 2: Add Institutional-Grade Signals (Week 2-3)

| Signal | Edge | Difficulty |

|-----|-----|-----|

| **\*\*Funding Rate\*\*** | When funding is extremely positive, shorts get paid → fade the crowd | Easy |

| **\*\*Open Interest spikes\*\*** | Sudden OI increase = new money entering → continuation signal | Easy |

| **\*\*Liquidation Heatmaps\*\*** | Large liquidation walls act as magnets for price | Medium |

| **\*\*Cross-exchange spread\*\*** | If Binance price > Bybit price → statistical arb opportunity | Medium |

| **\*\*On-chain whale alerts\*\*** | Large BTC movements to exchanges = sell pressure | Hard |

#### Quick Win — Funding Rate Filter:

```python

Don't go LONG when funding rate > 0.05% (market too bullish, reversal likely)

Don't go SHORT when funding rate < -0.05% (market too bearish, bounce likely)

funding = get_funding_rate("BTCUSDT")

if signal == "BUY" and funding > 0.0005:

 signal = "HOLD" # Skip — too crowded

...

Phase 3: Portfolio-Level Risk Management (Week 3-4)

| Feature | What It Does |
|----------------------------|---|
| ***Daily Loss Limit** | Stop trading if daily PnL drops below -2% of portfolio |
| ***Correlation Monitor** | If BTC and Gold correlation > 0.8, reduce position sizes (no diversification) |
| ***Max Open Positions** | Never have more than 3 simultaneous positions |
| ***Trailing Stop Loss** | Move SL to breakeven after price moves 1× ATR in your favor |
| ***Partial Profit Taking** | Close 50% at 1.5× ATR, let 50% run to 3× ATR |

Phase 4: Proper Backtesting Framework (Week 4-5)

Your current backtest shows 100% win rate — **this is a red flag, not a good sign.** A proper backtest needs:

| Element | Current | Need |
|-----------------------------|---------|--|
| ***Transaction costs** | None | Include 0.06% maker + 0.1% taker fees |
| ***Slippage modeling** | None | Add 0.02-0.05% slippage per trade |
| ***Walk-forward testing** | None | Optimize on Month 1-3, test on Month 4, roll forward |
| ***Monte Carlo simulation** | None | Randomize trade order 10,000× to test robustness |
| ***Benchmark comparison** | None | Compare vs Buy-and-Hold — if you can't beat it, why trade? |

Phase 5: Go Live Properly (Month 2)

| Step | Action |
|------|---|
| 1 | Deploy trading bot on a cloud VPS (DigitalOcean \$6/mo or Oracle Free Tier) |
| 2 | Run paper trading for 2-4 weeks to validate real-time performance |
| 3 | Start with minimum position sizes (\$10-50 per trade) |
| 4 | Scale up ONLY after 100+ live trades with positive expectancy |
| 5 | Add Telegram alerts for every trade (you already have the code from a previous conversation) |

The One Thing That Matters Most

> **"The strategy is 20% of success. Risk management is 80%."**

Your current system has a decent structure but is running the most basic strategy possible. The #1 priority is:

■ Immediate Action: Add Market Regime Detection + Funding Rate Filter

These two additions would transform your system from "retail hobby bot" to "semi-professional trading system" and cost you zero money — just code changes.

Would you like me to implement any of these phases right now?

Research-Backed Roadmap v2 (2026)

This section is append-only and does not change prior completed sections.

Phase A — Signal Quality Upgrades (Regime + Flow-Aware)

1. Add market regime classifier (trend/range/high-vol/crash) using ADX + ATR percentile + realized volatility.
2. Add derivatives flow filters:
 - funding-rate extreme filter (avoid crowded side)
 - open-interest expansion + price direction confirmation
3. Add session/liquidity filter (skip weak-liquidity windows unless volatility setup is strong).

****Why this matters****

- Improves signal selectivity and reduces whipsaw entries in non-trending conditions.

****Acceptance KPI****

- Reduce false-entry rate by $\geq 20\%$ vs current baseline over 60+ days paper data.
- Keep or improve profit factor after transaction costs.

Phase B — Execution and Slippage Controls

1. Add execution policy layer:
 - IOC market for urgent exits
 - optional passive/limit entry for lower slippage windows
2. Add slippage budget:
 - reject/resize entries when expected slippage > threshold.
3. Add exchange health gate:
 - require ``check_connection().can_trade == true`` before execution.
4. Persist execution-quality metrics per trade:
 - expected vs realized entry/exit price,
 - fill latency,
 - fee paid.

****Why this matters****

- Strategy edge is often lost at execution; controlling implementation shortfall is critical.

****Acceptance KPI****

- Keep realized slippage within configured budget in $\geq 90\%$ of trades.
- Track and report execution-quality metrics for 100% of closed trades.

Phase C — Portfolio Risk and Kill-Switch Policy

1. Add portfolio-level risk limits:
 - max daily loss,
 - max open positions,
 - correlated exposure cap (BTC/XAU/XAG dynamic correlation threshold).
2. Add adaptive risk sizing:
 - scale risk-per-trade down when rolling drawdown rises.
3. Keep fail-safe modes (A/B/C) and test each weekly:
 - A hard stop,
 - B paper fallback,
 - C retry-then-stop.
4. Add explicit incident states:
 - ``degraded``, ``blocked_auth``, ``blocked_latency``, ``blocked_risk``.

****Why this matters****

- Portfolio survival and stable drawdown control dominate long-term strategy viability.

****Acceptance KPI****

- Max intraday drawdown breach events: 0 in paper cycle.
- Fail-safe mode behavior deterministic and logged for every trigger.

Phase D — Validation Standards and Anti-Overfitting

1. Enforce walk-forward optimization as default:
 - rolling train/test windows,
 - no single split approvals.
2. Add robustness testing:
 - parameter stability checks,
 - reality-check style model comparison to combat data snooping.
3. Add baseline benchmarks:
 - buy-and-hold,
 - naive momentum,
 - random-timed entry control.
4. Add minimum sample requirements before promotion:
 - min trades per asset,
 - min out-of-sample window count.

****Why this matters****

- Prevents false confidence from overfit backtests and unstable parameter sets.

****Acceptance KPI****

- Strategy must beat benchmark set after fees/slippage in $\geq 70\%$ of walk-forward windows.
- Parameter set passes stability threshold across assets/time slices.

Phase E — Deployment, Monitoring, and SLOs

1. Define production SLOs:
 - uptime target,
 - order ack latency target,
 - stale-signal tolerance.
2. Extend local monitor to operational dashboard:
 - state timeline,
 - alert reasons,
 - fail-safe transitions,
 - connectivity and order reject analytics.
3. Add alerting:
 - Telegram/Slack for entry/exit, kill-switch, auth failures, stale data.
4. Add weekly review report:
 - pnl decomposition (signal vs execution),
 - top failure reasons,
 - mode A/B/C comparison summary.

****Why this matters****

- Most live failures are operational, not purely model-related.

****Acceptance KPI****

- Alert coverage for 100% critical incidents.

- Weekly report generated automatically with no manual edits.
